## Situation 02: Parametric Drawings

Prepared at Penn State  
Mid-Atlantic Center for Mathematics Teaching and Learning  
01 June 2005 – Rose Zbiek

Edited at University of Georgia  
Center for Proficiency in Teaching Mathematics  
21 February 2007 – Eileen Murray

### **Prompt**

This example, appearing in CAS-Intensive Mathematics (Heid and Zbiek, 2004)<sup>1</sup>, was inspired by a student mistakenly grabbing points representing both parameters (A and B in  $f(x) = Ax + B$ ) and dragging them simultaneously (the difference in value between A and B stays constant). This generated a family of functions that coincided in one point. Interestingly, no matter how far apart A and B were initially, if grabbed and moved together, they always coincided on the line  $x = -1$ .

### **Commentary**

In this case, GSP was a vehicle that brought mathematical relationships to the fore. When one sees such a phenomenon, one can enhance their experience by noticing the potential for mathematics in the patterns that are seen.

Focus 1 will show how the graphical phenomenon can be explained using a symbolic proof. Focus 2 will then show the extension of the phenomenon to quadratic functions (which also appears in CAS-Intensive Mathematics). This focus will show how this can also extend to a polynomial of higher degree (which generated another interesting relationship along with its proof).

### **Mathematical Foci**

#### **Mathematical Focus 1**

*Graphical phenomenon can frequently be explained using symbolic proof.*

Figure 1 displays a screen dump after A and B have been simultaneously dragged.

---

<sup>1</sup> Heid, M. K. & Zbiek, R. M. (2004). The CAS-Intensive Mathematics Project. NSF Grant No. TPE 96-18029

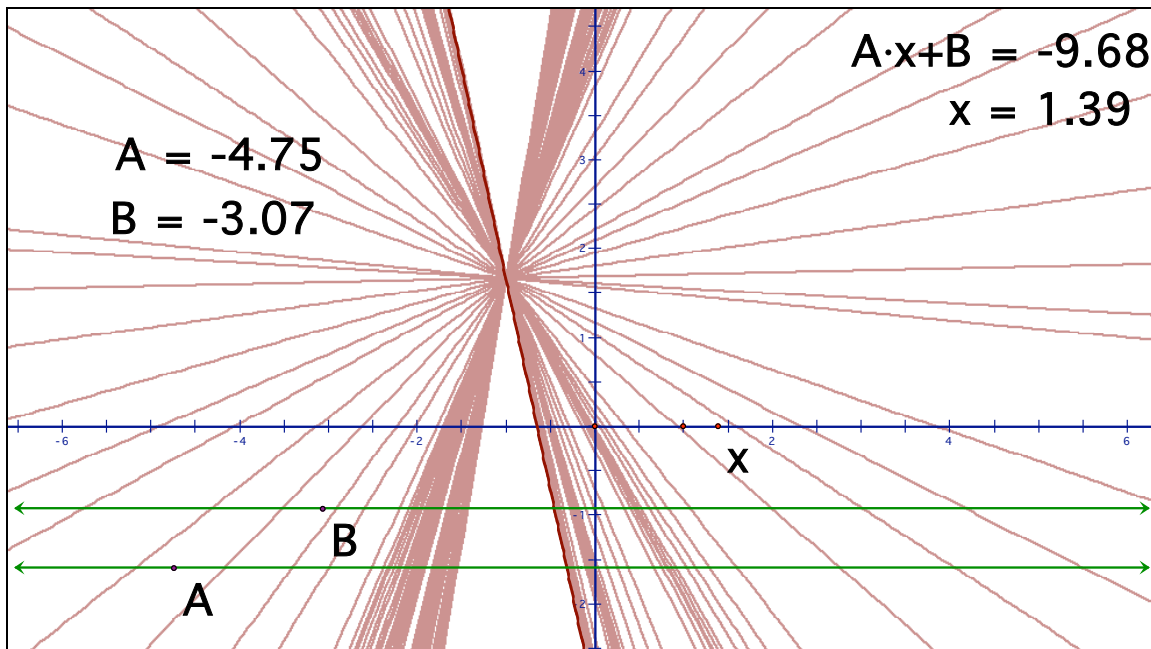

Figure 1. Screen dump showing trace of  $f(x) = Ax + B$  after  $A$  and  $B$  have been dragged simultaneously.

Notice that the family of lines that appear intersect on the line  $x = -1$ . To explain why this will be the case for any value of  $A$  and  $B$  where their difference remains constant can be explained using the following symbolic proof:

Let  $y = Ax + B$  and suppose  $A - B = k$ , a constant. Let  $y_1 = A_1x + B_1$  and  $y_2 = A_2x + B_2$  be two lines in this family.  $A_1 - B_1 = k = A_2 - B_2 \Rightarrow A_1 - A_2 = B_1 - B_2$ . Thus, to determine the point of intersection,  $y_1$  is set equal to  $y_2$ . Therefore,

$$\begin{aligned}
 A_1x + B_1 &= A_2x + B_2 \\
 (A_1 - A_2)x &= B_2 - B_1 \\
 x &= \frac{B_2 - B_1}{A_1 - A_2} = \frac{-(B_1 - B_2)}{A_1 - A_2} = -1
 \end{aligned}$$

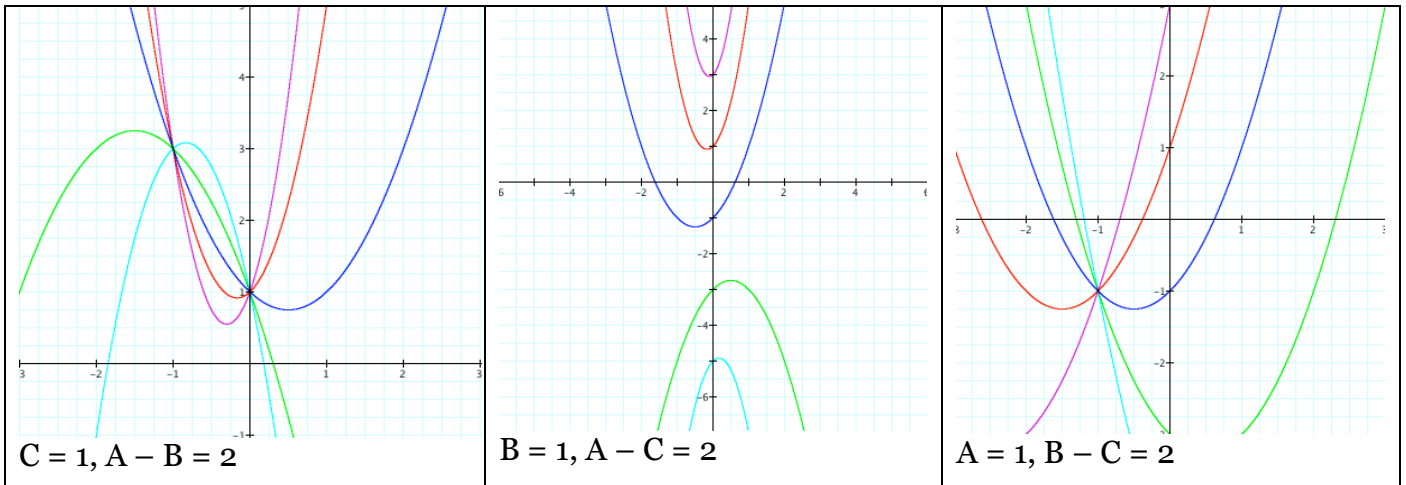

Hence, and two lines in this family will intersect at the point  $(-1, k)$ .

### Mathematical Focus 2

*Many times phenomena that are observed for certain functions can be extended to other functions with similar properties, i.e. linear functions extended to polynomial functions with degree  $> 1$ .*

When looking at quadratic functions, additional assumptions must be made to investigate the phenomenon. In a quadratic function, there are three coefficients rather than two (like in the linear function). For example, if  $y = Ax^2 + Bx + C$ , there are three possibilities to consider. Either we hold  $C$  constant with  $A - B = k$ ,  $B$  constant with  $A - C = k$ , or  $A$  constant with  $B - C = k$ . In each of these cases, similar symbolic proofs as the one in Focus 1 can be worked and the following conclusions can be drawn:

1. If  $C$  is held constant, there will be two intersections at  $(0, C)$  and  $(-1, k + C)$ .
2. If  $B$  is held constant, there will be no intersection because the equations reduce to  $x^2 = -1$ .
3. If  $A$  is held constant, there will be one intersection at  $(-1, A - k)$

This idea can now be extended for polynomials of the  $n^{\text{th}}$  degree. In order to do this extension, all but two coefficients are held constant and the remaining two have a constant difference. Consider the polynomial  $y = A_n x^n + A_{n-1} x^{n-1} + A_{n-2} x^{n-2} + \dots + A_2 x^2 + A_1 x + A_0$ . Choose 2 coefficients to vary, but keep their difference constant. All other coefficients will be held constant. Suppose  $A_j - A_i = k, i < j$ . If we have two polynomials in this family, we can determine where they will intersect by setting them equal to each other. Using a symbolic proof we see that the intersections will occur at the following points:

$$x^i = 0, y = A_0$$

$$x^{j-i} = -1, y = A_n (-1)^n + A_{n-1} (-1)^{n-1} + \dots + A_0$$

However, depending on the values of  $i$  and  $j$ , these points may or may not be defined. Specifically,  $x^{j-i} = -1$  will be defined as a real number only where  $j - i$  is an odd number.
