# Write-up 12: Interesting Relationships between Terms in the Fibonacci Sequence 

David Hornbeck

November 11, 2013

Many are (and should be) familiar with the famous Fibonacci sequence,

$$
1,1,2,3,5,8,13,21,34,55,89, \ldots
$$

or, defined recursively,

$$
\begin{gathered}
F_{0}=1, F_{1}=1 \\
F_{n+1}=F_{n}+F_{n-1}, n \geq 1
\end{gathered}
$$

One of the most fundamental features of the Fibonacci sequence is the limit of the ratio of its consecutive terms. This limit is represented by

$$
L=\lim _{n \rightarrow \infty} \frac{f_{n+1}}{f_{n}}
$$

Because the sequence is infinite, we could equivalently represent its limit as such:

$$
\lim _{n \rightarrow \infty} \frac{f_{n+2}}{f_{n+1}}
$$

Setting these two expressions for the limit of the ratio of consecutive terms of the sequence equal to each other,

$$
\begin{aligned}
L= & \lim _{n \rightarrow \infty} \frac{f_{n+1}}{f_{n}}=\lim _{n \rightarrow \infty} \frac{f_{n+2}}{f_{n+1}} \\
& =\lim _{n \rightarrow \infty} \frac{f_{n}+f_{n+1}}{f_{n+1}} \\
& =\lim _{n \rightarrow \infty}\left(\frac{f_{n}}{f_{n+1}}+1\right) \\
& =1+\lim _{n \rightarrow \infty} \frac{1}{\frac{f_{n+1}}{f_{n}}}
\end{aligned}
$$

$$
=1+\frac{1}{L}
$$

Hence,

$$
\begin{aligned}
& L=1+\frac{1}{L} \\
\Rightarrow & L^{2}=L+1 \\
\Rightarrow & L=\frac{1+\sqrt{5}}{2}
\end{aligned}
$$

(Note: $L \neq \frac{1-\sqrt{5}}{2}<0$ because $f_{n}>0 \forall n$.) This $L$ is the well known $\phi$, or the golden ratio (approximately 1.61803399...). Using Excel, we can explore this golden ratio and examine other interesting ratios within the Fibonacci sequence.
For instance, what is the ratio between every second terms, i.e. what is

$$
\lim _{n \rightarrow \infty} \frac{f_{n+2}}{f_{n}}
$$

What about every third term? Fourth, fifth, etc.? Using Excel, we can produce the following spreadsheet (Figure 1) with these ratios as $n$ increases.

We generate these values using very simple functions in the first possible row of each column and then dragging that formula throughout the rows of each column; note that, for example, calculating the ratio between third terms requires starting with the fourth value of the Fibonacci sequence.
It is clear that the ratio of every third terms is not $\phi$; in fact, each ratio increases as the terms spread farther apart. Intuitively, this is clear from the increasing nature of the Fibonacci sequence. Further, we can notice that the ratio of every second term is $1+\phi$; can we prove this?

$$
\begin{gathered}
\lim _{n \rightarrow \infty} \frac{f_{n+2}}{f_{n}} \\
=\lim _{n \rightarrow \infty} \frac{f_{n}+f_{n+1}}{f_{n}} \\
=\lim _{n \rightarrow \infty} 1+\frac{f_{n+1}}{f_{n}} \\
=1+\lim _{n \rightarrow \infty} \frac{f_{n+1}}{f_{n}} \\
=1+\phi
\end{gathered}
$$

| - | A | B | C | D | E | F |

Figure 1: Figure 1: The Fibonacci sequence \& ratios of consecutive, second, third, fourth, and fifth terms

We now may have a new interesting sequence developing. Let us create the following notation:

$$
\begin{gathered}
F_{0}^{*}=\lim _{n \rightarrow \infty} \frac{f_{n+1}}{f_{n}}=\phi \\
F_{1}^{*}=\lim _{n \rightarrow \infty} \frac{f_{n+2}}{f_{n}}=1+\phi
\end{gathered}
$$

From the Excel spreadsheet, we can estimate what the limit of the ratio of third terms, or

$$
F_{2}^{*}=\lim _{n \rightarrow \infty} \frac{f_{n+3}}{f_{n}}
$$

by calculating the difference between columns C and D for relatively large $n$.

$$
D 41-C 41=4.236068-2.618034=1.618034
$$

Approximately a difference of $\phi$ ! Therefore, we should have $F_{2}^{*}=1+2 \phi$. Upon further investigation, we can indeed prove that

$$
\begin{gathered}
F_{2}^{*}=\lim _{n \rightarrow \infty} \frac{f_{n+3}}{f_{n}} \\
=\lim _{n \rightarrow \infty} \frac{f_{n+1}+f_{n+2}}{f_{n}} \\
=\lim _{n \rightarrow \infty} \frac{f_{n+1}}{f_{n}}+\lim _{n \rightarrow \infty} \frac{f_{n+2}}{f_{n}} \\
=F_{0}^{*}+F_{1}^{*} \\
=\phi+(1+\phi) \\
=1+2 \phi
\end{gathered}
$$

Thus far, it appears that the sequence of limits of ratios of Fibonacci numbers defined by

$$
\begin{gathered}
\left\{F^{*}(n)\right\}_{0}^{\infty} \\
F_{0}^{*}=\phi, F_{1}^{*}=1+\phi
\end{gathered}
$$

behaves identically as the Fibonacci sequence. Further, considering that $F_{1}^{*}=1+\phi$ and $F_{2}^{*}=2+\phi$, it appears that our new sequence $F_{n}^{*}$ could also be written as a sum of two sequences:

$$
F_{n}^{*}=F_{n}+\phi F_{n+1}
$$

First, let's examine if the Excel spreadsheet can confirm this for $F_{3}^{*}$ and $F_{4}^{*}$.

$$
E 41-D 41=6.854102-4.236068=2.618034 \approx 1+\phi
$$

$$
F 41-E 41=11.09017-6.854102=4.236068 \approx 1+2 \phi
$$

Given our previous values of $F_{n}^{*}$, we can now claim

$$
\begin{aligned}
& F_{3}^{*}=2+3 \phi=F_{3}+\phi F_{4} . \\
& F_{4}^{*}=3+5 \phi=F_{4}+\phi F_{5}
\end{aligned}
$$

Let us now try to prove the following claim, which would be a somewhat intuitive, but rather interesting statement as to the nature of how the Fibonacci sequence works beyond its most basic properties.

Claim: $F_{n}^{*}=F_{n}+\phi F_{n+1}$
Proof: We will use strong mathematical induction.
Base case: $k=2$
As shown above, $F_{2}^{*}=1+2 \phi=F_{2}+\phi F_{3}$.
Induction hypothesis: Suppose $F_{m-1}^{*}=F_{m-1}+\phi F_{m}$ for all $k \in\{3,4, \ldots, k-1\}$. Then,

$$
\begin{gathered}
F_{k}^{*}=\lim _{n \rightarrow \infty} \frac{F_{n+k+1}}{F_{n}} \\
=\lim _{n \rightarrow \infty} \frac{F_{n+k-1}}{F_{n}}+\frac{F_{n+k}}{F_{n}}\left(\text { by def'n of } F_{n}\right) \\
=F_{k-2}^{*}+F_{k-1}^{*}\left(\text { by def'n of } F_{n}^{*}\right) \\
=\left(F_{k-2}+\phi F_{k-1}\right)+\left(F_{k-1}+\phi F_{k}(\text { by induction hypothesis })\right. \\
=\left(F_{k-2}+F_{k-1}\right)+\phi\left(F_{k-1}+F_{k}\right) \\
=F_{k}+\phi F_{k+1}\left(\text { by def'n of } F_{n}\right)
\end{gathered}
$$

Therefore, $F_{n}^{*}=F_{n}+\phi F_{n+1}$ for all $n \in \mathbb{N} \backslash\{1\}$.
