Point of Concurrency and (more) Circumcircle

Problem #1:

This first problem is taken from NCTM's <u>Illumination project</u>. An interactive version of the exploration could be found <u>here</u>.

Use the following steps on GSP to construct a circumcircle:

- 1. Construct the <u>perpendicular bisector</u> of each side of the triangle.
- 2. Label the intersection of the bisectors point *O*. This point is the circumcenter of the triangle. (Note that all three perpendicular bisectors meet at the same point; therefore, it would have been sufficient to only construct two of the perpendicular bisectors in Step 1 to identify the circumcenter.)
- 3. Using O as the center, construct a circle that passes through the vertices of the triangle.

Point *M* is the midpoint of *AB*, and *O* is the circumcenter of triangle *ABC*. The circumcircle with center O and radii *OA* and *OB* has been constructed.

<u>Question 1</u>: Triangles OAM and OBM are congruent. Do you see why?

Question 2: What does this mean about OA and OB?

<u>Question 3</u>: What about OC? How is it related to OA and OB?

<u>Question 4</u>: What does this prove about the circle?

Problem #2:

Your family is considering moving to a new home. The diagram shows the locations of where your parents work and where you go to school. The locations form a triangle.

In this diagram, how could you find a point that is equidistant from each location? Explain your answer.

Make a sketch, by hand, of the situation. Indicate the best location for the new home.
